## Abstract

In this paper, the properties of a catalyst that composed of magnetic nanoparticles and Pectin biopolymer that is widely found in nature ( $\text{Fe}_3\text{O}_4@$ Pectin) to support nickel (II) acetate are discussed, and this catalyst was then used in response to the synthesis of aldehyde derivatives. The heterogeneous catalyst was characterized by techniques such as FT-IR spectroscopy, FE-SEM, TEM, XRD spectroscopy, EDX spectroscopy and ICP spectroscopy. Then the catalyst was explored in the oxidation reaction of alcohols that has high efficiency and selectivity and the synthesized aldehydes. The most important advantages of this method are easy to work up procedure, perform the reaction in solvent-free conditions, and the catalyst can be separated by an external magnet and used several times without reducing the activity, which prevents environmental pollution.

## Introduction

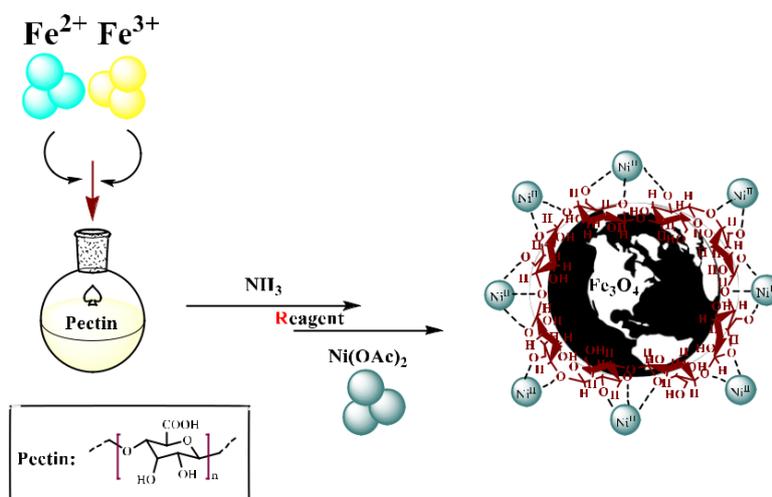

Oxidation reactions are ubiquitous in the pharmaceutical and fine-chemical industries, and are fundamentally important for introducing oxygen-rich functional groups to organic molecules. For example, aldehyde and ester-containing molecules are heavily employed as flavouring and fragrance agents owing to their volatility and distinctly aromatic nature they are often pleasing to smell and taste [1]. Benzaldehyde is a key component for most almond-based flavourings, although it finds other uses as a precursor for plastic additives and as an intermediate in the synthesis of antibiotic drugs such as chloramphenicol and ampicillin, as well as stimulants like ephedrine [2]. On the other hand, in recent years, extensive studies have been done on

gbagherzade@gmail.com, bagherzadeh@birjand.ac.ir the design and development of green catalysts, thereby taking useful steps to protect the environment [3, 4]. The important advantages of heterogeneous catalysts that have recently attracted the attention of scientists include easy separation, low waste generation, reduced cost, and the ability to recover catalysts from reaction environments [5-7]. The magnetic nanoparticles are a class of advanced nanomaterials with specific applications, properties, and sizes. Applications of these nanoparticles can be described as magnetic drug carriers, magnetic cell separators, and biological sensors, these nanoparticles are used in the treatment of some cancers [8-11]. Magnetic nanoparticles are highly efficient in the synthesis of heterogeneous catalysts due to their biological, biomedical, environmental, low toxicity, and cost-effective properties [12]. On the other hand, the choice of supporting materials for catalytic reactions is very important, because they

\* Corresponding Author's e-mail:

determine the amount of activity, thermal durability, and reproducibility of the catalyst [13]. Hence, the synthesis of biopolymer and magneto-based nanocomposites such as  $\text{Fe}_3\text{O}_4$  as a substrate for the catalyst is of particular importance due to its large surface area, ease of preparation, and green nature [14]. Pectin is a sugar-acid polymer that is extracted from fruits and vegetables and its main chemical constituent is galacturonic acid. Pectin has a complex structure that depends on the source and the extraction process; it also has properties such as biodegradable, biocompatible, and bioactive. Pectin is used in foods, cosmetics, medicine, and biology. Due to the presence of carboxylate groups in the structure of pectin, these compounds can be coordinated with metals [15]. Khazaei and other [16] used pectin for supporting Pd-nanoparticles for the catalysis of Heck coupling. Research results Douskhah and other [17] that used magnetic pectin to support Cu (II) in the click reaction showed that catalyst herein is a recyclable and sustainable catalyst in the click synthesis. Talat Baran [13] used pectin-supported palladium as the catalyst for Suzuki-Miyaura coupling reactions. Herein, the goal of our research team is to provide a novel multi-core catalyst that has high power, short reaction time, recyclable in multi-stage and non-toxic reactions. This protocol from

both the economic and synthetic point of view with several advantages like reduced pollution, lower cost, and simplicity in processing, which are beneficial to the industry as well as to the environment. In this work, due to the importance of  $\text{Fe}_3\text{O}_4$  and pectin and the novelty of this polymer, we are encouraged to synthesize a core/shell catalyst with  $\text{Fe}_3\text{O}_4$  and pectin and also use nickel metal, which has not been studied on pectin in the past. This natural and green substrate. Pectin, due to its features such as eco-friendly, safe, nontoxic, nonflammable, clean, green, inexpensive as well as readily available. Therefore, the metal is well placed on the metal cavities covered with pectin to have high performance and resistance to the synthesis of aldehydes, which these compounds have good medicinal properties. Herein, we have developed a reaction to prepare aldehyde's analogs using alcohol and Ni (II) supported  $\text{Fe}_3\text{O}_4$ @Pectin is effective as a novel catalyst and inexpensive based on green chemistry. This catalyst  $\text{Fe}_3\text{O}_4$ @Pectin@Ni (II) greatly reduced the cost of this transformation, and the resulted operation and work-up procedures were greatly simplified.

**Scheme1:** The synthesis route for  $\text{Fe}_3\text{O}_4$ @Pectin@Ni (II)

## Experimental section and procedures:

### Material and instruments

Ferric chloride hexahydrate ( $\text{FeCl}_3 \cdot 6\text{H}_2\text{O}$ , >99%) and ferrous chloride tetrahydrate ( $\text{FeCl}_2 \cdot 4\text{H}_2\text{O}$ ) were used as an iron source. Pectin with the degree of esterification of 76% and other of the materials used in this article were from Merck (Germany) and Sigma Aldrich and were used without further purification. The reaction progress and purity of the products were determined using TLC on silica-gel Polygram SILG/UV254 plates. FT-IR spectra were recorded with a Nicolet system

800 beam splitter KBr SCAL = 800 in the range 400– 4000  $\text{cm}^{-1}$ . Transmission electron microscope (TEM) investigations were performed using a Philips EM 208S Transmission Electron Microscope. The powder X-ray diffraction (XRD) was performed within Philips PW1730 with a Cu  $\text{K}\alpha$  ( $\lambda = 1.54060 \text{ \AA}$ ) radiation. SEM-EDX were recorded by Fe-SEM TESCAN MIRA3.

### Synthesis of $\text{Fe}_3\text{O}_4$ @Pectin

Synthesis of  $\text{Fe}_3\text{O}_4$ @Pectin was performed with a little modification [18]. According to this, 0.5 g of

pectin dissolve in 50 ml of distilled water under stirring until a homogeneous dispersion of pectin is obtained.  $\text{FeCl}_3 \cdot 6\text{H}_2\text{O}$  (3 g) and  $\text{FeCl}_2 \cdot 4\text{H}_2\text{O}$  (1.6 g) dissolve in 25 ml of distilled water separately and then add them. Then slowly added them to the mixture containing pectin which resulted in a brown gel. The reaction mixture was stirred under a gentle flow of  $\text{N}_2$  at  $85^\circ\text{C}$  for 2 h. After which an excess of ammonium hydroxide (25 wt%) to the reaction mixture was added until the pH reaches 11-12 and the mixture becomes black indicating the formation of magnetite and again the mixture was under a gentle flow of  $\text{N}_2$  at  $85^\circ\text{C}$  for 30 min. Finally, the precipitate was separated by an external magnet and washed with distilled water several times until the pH dropped to approximately 7 then dried under vacuum.

#### Synthesis of $\text{Fe}_3\text{O}_4$ @Pectin @Ni (II)

The synthesis of  $\text{Fe}_3\text{O}_4$ @Pectin @ Ni is performed by the saturation method [17]. Based on this method, an excess amount of nickel (II) acetate dissolve in 5 ml of ethanol, then add 1 g of  $\text{Fe}_3\text{O}_4$ @Pectin to the solution and allow to react for 12 h under vigorous stirring. Finally, it separated the solid product from the solution and washed it with ethanol several times and dried under vacuum at  $60^\circ\text{C}$ .

#### The method of synthesizing aldehyde derivatives

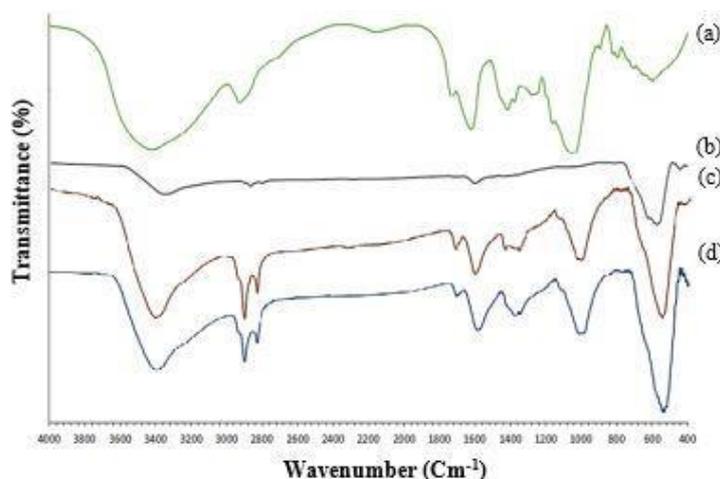

The method of synthesizing aldehyde derivatives: Benzyl alcohol (1.0 mmol), TBHP (2.0 mmol), catalyst (1.25 mol %) were placed in a test tube on a stirrer at  $65^\circ\text{C}$  for 90 minutes under solvent-free condition.

#### Result and discussion:

##### Catalyst synthesis/characterization

The catalyst synthesis was very efficient and simple for the reaction of the synthesis of aldehyde derivatives from alcohol. We used pectin to synthesize the catalyst because pectin is a biopolymer that is widely found in nature. Pectin has carboxylic acid groups that can act as a covalently chelating agent to  $\text{Fe}_3\text{O}_4$  nanoparticles and direct the nanostructure. A general schematic for the synthesis of  $\text{Fe}_3\text{O}_4$ @Pectin@Ni (II) is shown (Scheme 1). The structure of the synthesized catalyst was characterized by various analyses like FT-IR, ICP, FE-SEM, XRD, and TEM.

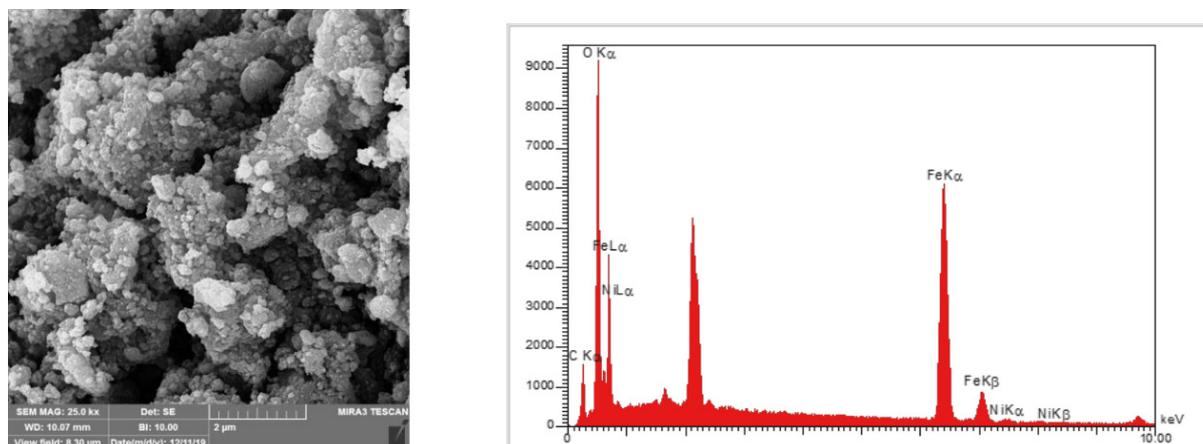

FT-IR spectra of  $\text{Fe}_3\text{O}_4$ , Pectin,  $\text{Fe}_3\text{O}_4$ @Pectin,  $\text{Fe}_3\text{O}_4$ @Pectin@Ni (II) catalyst are given in (Figure. 1). FT-IR spectrum of Pectin (Fig. 1a) shows characteristic peaks at  $3400\text{-}3600\text{ cm}^{-1}$  (O-H stretching alcoholic and acidic),  $2923\text{ cm}^{-1}$  (C-H stretching),  $1725\text{ cm}^{-1}$  (C=O of ester),  $1618\text{ cm}^{-1}$  ( $\text{COO}^-$  asymmetric stretching),  $1412\text{ cm}^{-1}$  ( $\text{COO}^-$  symmetric stretching), The FT-IR spectrum of  $\text{Fe}_3\text{O}_4$  (Figure. 1b) the stretching vibrations Fe-O and O-H at  $574\text{ cm}^{-1}$  and  $3420\text{ cm}^{-1}$  that allow the establishment of  $\text{Fe}_3\text{O}_4$  nanoparticles. After core-shell the Pectin with  $\text{Fe}_3\text{O}_4$ , shows the peaks at  $3422\text{ cm}^{-1}$  (O-H stretching),  $2923\text{ cm}^{-1}$  (C-H stretching),  $1626\text{ cm}^{-1}$  ( $\text{COO}^-$  asymmetric stretching) and  $577\text{ cm}^{-1}$  can be assigned to  $\text{Fe}_3\text{O}_4$  (Figure.1c), in addition to the above-mentioned bands, complexation of Nickel ions to  $\text{Fe}_3\text{O}_4$ @Pectin causes absorption to lower wave O-H stretching  $3418\text{ cm}^{-1}$  and  $\text{COO}^-$  asymmetric stretching  $1622\text{ cm}^{-1}$  Indicates the involvement of the OH group along with the  $\text{COO}^-$  in bonding with the nickel metal and confirming the coordination through the oxygen group drawn to the metal (Figure.1d).

**Figure 1:** FT-IR spectra of a) Pectin, b)  $\text{Fe}_3\text{O}_4$ , c)  $\text{Fe}_3\text{O}_4$ @Pectin, d)  $\text{Fe}_3\text{O}_4$ @Pectin@Ni (II)

Due to the importance of heterogeneous catalysts, we used Fe (III) and Fe (II) to magnetize the catalyst, that structure is core-shell according to SEM results. EDX analysis (Figure. 2) shows the logical type of percentages of Fe, C, O, Ni atoms in  $\text{Fe}_3\text{O}_4@Pectin@Ni(II)$  catalyst. The SEM image

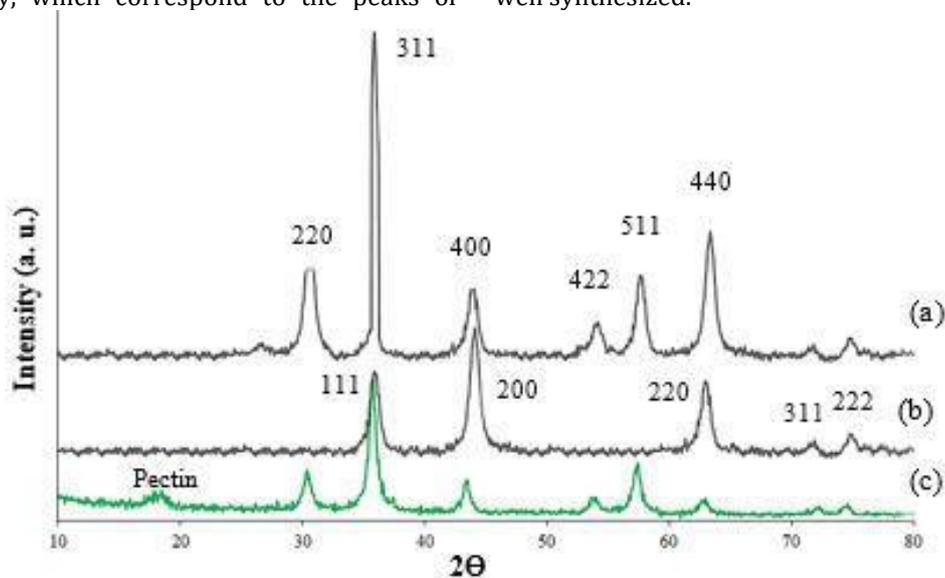

and elemental analysis of  $\text{Fe}_3\text{O}_4@Pectin@Ni(II)$  complex were characterized by SEM, EDX. The SEM image of the  $\text{Fe}_3\text{O}_4@Pectin@Ni(II)$  complex indicated the formation of the desired complex.

**Figure 2:** SEM image and EDS spectra of  $\text{Fe}_3\text{O}_4@Pectin@Ni(II)$

Figure 3 shows the XRD spectrum for the  $\text{Fe}_3\text{O}_4$ , Ni (II),  $\text{Fe}_3\text{O}_4@Pectin@Ni(II)$  catalyst. The spectrum of  $\text{Fe}_3\text{O}_4@Pectin@Ni(II)$  catalyst shows peaks at  $30.51^\circ$ ,  $35.81^\circ$ ,  $43.21^\circ$ ,  $54.06^\circ$ ,  $56.91^\circ$ ,  $62.46^\circ$  degrees, respectively, which correspond to the peaks of

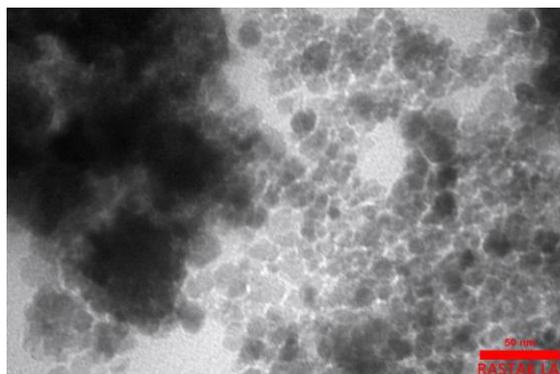

$\text{Fe}_3\text{O}_4$  and Ni (II). Also, the peak at  $18^\circ$ , which is related to magnetized pectin, indicates that it is also present in the structure of the pectin catalyst. Therefore, it can be concluded that the catalyst is well synthesized.

**Figure 3:** XRD of a)  $\text{Fe}_3\text{O}_4$  b) Ni (II) c)  $\text{Fe}_3\text{O}_4@Pectin@Ni(II)$

TEM images show a biopolymer network of pectin as well as encapsulated  $\text{Fe}_3\text{O}_4$  nanoparticles, that supporting Nickel (II) acetate on  $\text{Fe}_3\text{O}_4@Pectin$  had no significant effect on its structure. The size of the

nanoparticles is about 6 to 25 nm and averages about 11 nm (Figure 4).

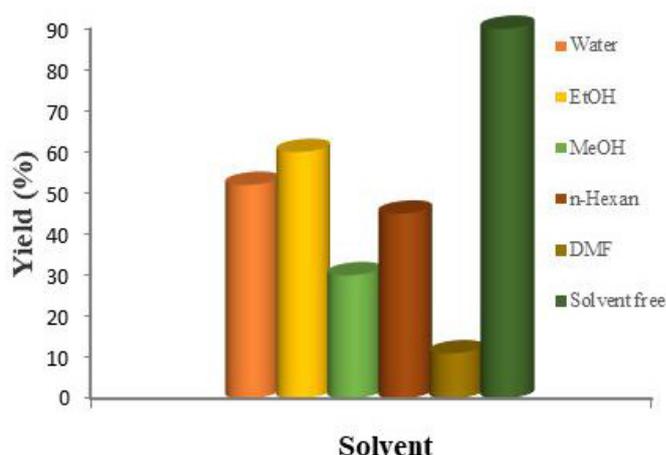

**Figure 4:** TEM images of the Fe<sub>3</sub>O<sub>4</sub>@Pectin @ Ni (II)

### 2.1. Catalytic activity studies

After investigating the properties of the Fe<sub>3</sub>O<sub>4</sub>@Pectin @ Ni (II) catalyst it was investigated its function in the synthesis reaction of aldehyde derivatives of alcohols. In this reaction, first, oxidation of the alcohols occurred in the presence of TBHP and catalysts to the aldehyde derivatives. Various conditions in this reaction were

investigated for the oxidation of benzyl alcohol to find an optimized condition for its reaction. The several solvents, the solvent-free state was more favorable than the other solvents in terms of product yields and green chemistry, water and ethanol are also green and suitable solvents for producing efficient benzaldehyde (Figure 5).

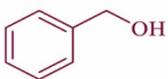

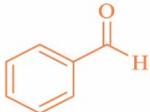

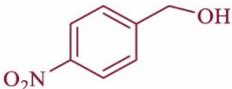

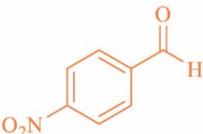

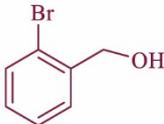

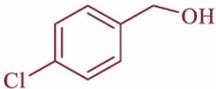

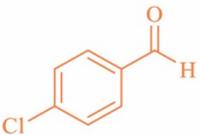

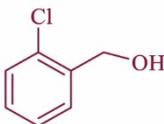

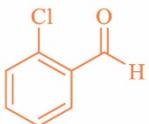

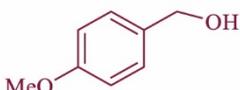

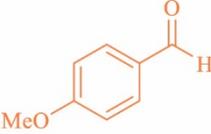

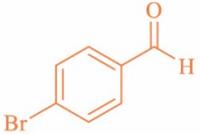

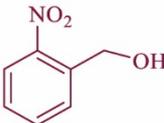

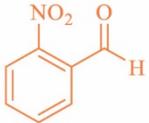

**Figure 5:** Screening of solvent for oxidation reaction with a molar ratio of benzyl alcohol, TBHP and Fe<sub>3</sub>O<sub>4</sub>@Pectin @ Ni (II), 65 °C

Various temperatures were investigated (from RT to 90 °C) and the best temperature for producing a high-efficiency product was 65°C and a quantity of catalyst (1.25 mole %) has good efficiency for the preparation of benzaldehyd.

After optimizing the reaction, the conditions for the oxidation of alcohol derivatives to benzaldehyde derivatives were investigated.

6			150	92
7			60	85
8			120	80

<sup>a</sup> Reaction conditions: alcohol (1 mmol), TBHP (2 mmol), Fe<sub>3</sub>O<sub>4</sub>@Pectin@ Ni (II) catalysed (1.25 mol%) at 65 °C and solvent-free.

<sup>b</sup> Isolated yield.

The study showed that the electron donor groups on the ring slow the reaction and reduce the yield, but the electron-withdrawing accelerates and increases the reaction yield. It also has good selectivity for the synthesis of benzaldehyde (Table 1).

Compared to other methods (Table 2), the method we chose is a milder, greener, and rapid pathway with higher conversion and selectivity towards the production of benzaldehyde from benzyl alcohol and this clearly shows that the proposed catalyst performs, the catalytic role well.

## Conclusion

In summary, a novel nanocomposite of a magnetic-based pectin biopolymer that widely found in nature successfully modified to form a catalyst support material for the support of Ni (II) using the carboxylate groups of the pectin. In other words, the Carboxylate groups in the pectin biopolymer were the main function in the support of Ni (II). Then the Fe<sub>3</sub>O<sub>4</sub>@Pectin @ Ni (II) catalyst, which is a heterogeneous catalyst, reacted to synthesize the aldehyde derivatives from alcohols under the terms of solvent-free and observation that the reaction has good efficiency. Also, the recycling test showed that the catalyst has a recyclable and stable property for the xanthine synthesis reaction.
